

TRICERATOPS

SPECIES NUMBER: GA-21268

FAMILY: CERATOPIDAE

DIET: FERNS, CYCADS, CONIFERS

HEIGHT: 7 FT

WEIGHT: 5 TONS

LENGTH: 33 FT

ANIMAL DESCRIPTION: Triceratops is one of the few horned animals on Isla Sorna and the only horned animal on Isla Nublar. This species travels in herds and are generally docile animals unless provoked or when protecting their young. The head is solid bone and is used as protection against larger carnivores. There are 15 known adults populating Isla Sorna. Breeding takes place once a year with less than half that number reaching maturity.

ANIMAL LOCATION: Triceratops are usually found grazing the low lands of the La Pradera and the Palo Blanco plains. They are rarely found in the upper La Quebrada plains because the Tyrannosaurus nesting grounds are nearby. Tagging should be done before dawn and near dusk, when the animals will less likely be on alert...
